

Temporal validation reveals workload-dependent energy opportunity

Three calendar-selected weeks | 4 clusters × 8 curve conditions × 3 allowances | fixed-size non-preemptive gangs

Each cell retains all background allocations and GPU idle. Homogeneous curve transfer and idle ratio 0.10 are assumptions.

May / July / September 2020 (month labels). Inference 48/32 curves coincide; conditions are correlated, not independent replicates.

Retrospective completion benchmarks with future allocations known. No actual SLA, useful-work calibration, node energy or grid benefit measured.
